

Problem 5: Shipping Cost Calculator

Name: _____

Function to write: `getShippingCost(weight, isMember)`Write a function `getShippingCost(weight, isMember)` that calculates shipping:

- If `isMember` is `true`: shipping is free if `weight <= 5`, otherwise \$3 flat.
- If `isMember` is `false`:
 - `weight <= 1` → \$5
 - `weight <= 5` → \$8
 - `weight > 5` → \$12

This one needs a conditional inside a conditional (nested). Start with the outer check on `isMember`, then handle the weight tiers inside each branch.

Test Cases — fill in the expected output before you run your code

#	Call	Expected Output
1	<code>getShippingCost(3, true)</code>	
2	<code>getShippingCost(8, true)</code>	
3	<code>getShippingCost(0.5, false)</code>	
4	<code>getShippingCost(4, false)</code>	
5	<code>getShippingCost(10, false)</code>	

HINT

Sketch out the branches on paper first — which combinations of `isMember` and `weight` give which price — before writing code.
